Abstract

Assuming the Higgs triplet model, we obtain the bounds on the absolute neutrino mass and the unknown MNS parameters by measuring decay processes of doubly charged particles at the CERN LHC. Majorana CP violating phases affect the prediction rather seriously, which is served to restrict these phases.

1 Introduction

Presently, observation of the Majorana nature of neutrinos and the absolute value of the neutrino mass is indispensable for constructing a concrete model for particle physics beyond the standard model (SM). For instance, renormalizable minimal SO(10) GUT predicts all of the parameters of the Maki-Nakagawa-Sakata (MNS) lepton mixing matrix [1] including the Dirac and Majorana phases unambiguously which plays an essential role to match up with the neutrino oscillation data [2]. However, these phases are still left unknown and the experimental observation of them is an important issue for near future experiments. The GUT model is the comprehensive theory and must explain the whole range of particle physics. On the other hand, the Higgs triplet model (HTM) [3] is the simplest extension of the SM which invokes the new phenomena of lepton physics. The HTM may be rather restrictive and may be interpreted as an effective theory. However, it makes us easier to extract an essential point of new physics if it works well. The HTM is also very interesting because it gives sizable effects on low energy lepton physics.

In [4] we showed that the HTM enables us to detect the Majorana property by the precise measurement of the usual muon decay. The interference terms in muon decay due to the Majorana property were first discussed in [5], but the detection of them was far beyond the present upper bound. On the contrary, the HTM gives a rather marginal value to the present precision order. In the literatures [6] it was discussed that the unknown MNS parameters may be solved by the observations at the CERN Large Hadron Collider (LHC) if the HTM works well. In the previous paper [7] we published a brief report on determining the lower bound of the minimal neutrino mass, equivalently, the absolute neutrino masses by measuring the ratio of decay widths of doubly charged Higgs boson to leptonic channels, $\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)}$, at the LHC. There it was shown that the Majorana phases play an essential role allowing this ratio to be both larger and smaller than 1. In this paper we develop the arguments in more detail and more general than [7].

In Sec. 2, we briefly explain the HTM and experimental situations on the considering process at the LHC. The lepton mixing matrix and the neutrino mass hierarchy are examined in Sec. 3. Numerical calculations are presented in Sec. 4. Finally, Sec. 5 is devoted to discussions.

2 The Higgs triplet model

The neutrino-Higgs coupling in the HTM is given by

$$\mathcal{L}_{\text{HTM}} = \overline{L^c} h_M i\tau_2 \Delta L + \text{H. c.} \quad (2.1)$$

Here $L \equiv (\nu_L, l_L)^T$ and $L^c \equiv C\overline{L}^T$, and neutrinos are required to be Majorana particles. The symmetric 3×3 matrix $(h_M)_{ll'}$ ($l, l' = e, \mu, \tau$) is the coupling strength and τ_i ($i = 1, 2, 3$) denote the Pauli matrices. The triplet Higgs boson field with hypercharge $Y = 2$ can be parameterized

by

$$\Delta = \begin{pmatrix} \Delta^+/\sqrt{2} & \Delta^{++} \\ \frac{v_\Delta}{\sqrt{2}} + \Delta^0 & -\Delta^+/\sqrt{2} \end{pmatrix}, \quad (2.2)$$

where v_Δ is the vacuum expectation value of the triplet Higgs boson. Mass eigenvalues of neutrinos are determined by diagonalization of $m_\nu = \sqrt{2}h_M v_\Delta$. There is a tree level contribution to the electroweak ρ parameter from the triplet vacuum expectation value as $\rho \approx 1 - 2v_\Delta^2/v^2$. The CERN LEP precision results can give an upper limit $v_\Delta \lesssim 5$ GeV. There is no stringent bound from the quark sector on triplet Higgs bosons because they do not couple to quarks.

The Yukawa interaction of the singly and the doubly charged Higgs bosons is written as

$$\begin{aligned} \mathcal{L}_\Delta = & -\sqrt{2}(h_M^\dagger U)_{\ell i} \bar{\ell}_L N_i^c \Delta^- \\ & - (h_M^\dagger)_{\ell' \ell} \bar{\ell}_L \ell'^c \Delta^{--} + \text{H.c.}, \end{aligned} \quad (2.3)$$

where

$$h_M = U m_\nu^{\text{diag}} U^T / (\sqrt{2} v_\Delta) \equiv \langle m_\nu \rangle_{ab} / (\sqrt{2} v_\Delta), \quad (2.4)$$

and $N_i (i = 1, 2, 3)$ represent Majorana neutrinos which satisfy the conditions $N_i = N_i^c = C \bar{N}_i^T$. The most stringent constraint on the triplet Yukawa coupling comes from $\mu \rightarrow ee\bar{e}$ through the tree-level contribution due to the doubly charged Higgs boson [8]. Thus the peculiar properties of the HTM appear in the processes of the doubly charged Higgs. Among them, we have a sizable cross section of $\Delta^{++} \rightarrow l_a l_b$ for $m_\Delta = O(100)$ GeV, and the decay width of the doubly charged Higgs boson to this leptonic channel is given by

$$\Gamma(\Delta^{++} \rightarrow l_a^+ l_b^+) = \frac{1}{4\pi(1+f)} |h_{ab}|^2 m_{\Delta^{++}}, \quad (2.5)$$

where $f = 1(0)$ for $a = b$ ($a \neq b$).

Searching for the neutrino mass in the HTM at the LHC was discussed in [6], where the event numbers were estimated at the scheduled energy and luminosity. Unfortunately, the LHC was forced to lower the energy scale 10 TeV and the luminosity $10^{33} \text{ cm}^{-2}\text{s}^{-1}$. The cross section for $pp \rightarrow \Delta^{++} \Delta^{--}$,

$$\begin{aligned} 99 & \quad \text{fb for } m_{\Delta^{++}} = 200 \text{ GeV}, \\ 5.9 & \quad \text{fb for } m_{\Delta^{++}} = 400 \text{ GeV}, \end{aligned} \quad (2.6)$$

for $\sqrt{s} = 14 \text{ TeV}$ is reduced to

$$\begin{aligned} 53 & \quad \text{fb for } m_{\Delta^{++}} = 200 \text{ GeV}, \\ 2.6 & \quad \text{fb for } m_{\Delta^{++}} = 400 \text{ GeV}, \end{aligned} \quad (2.7)$$

for $\sqrt{s} = 10 \text{ TeV}$ [7].

The first 100-day run at low luminosity resulted the integrated luminosity 10 fb^{-1} . So we may have a sizable number of events even in this case, though the final number of ll events depends on the $\text{Br}(\Delta \rightarrow ll)$. The decay width to the other channel, WW channel is

$$\Gamma(\Delta^{--} \rightarrow W^- W^-) \approx \frac{v_\Delta^2 m_{\Delta^{++}}^3}{2\pi v^4} \equiv c v_\Delta^2, \quad (2.8)$$

(full expression is given in [9]) and the branching ratio is given by

$$\text{Br}(\Delta \rightarrow l_a l_b) \equiv \text{Br}_{ab} = \frac{|\langle m_\nu \rangle_{ab}|^2}{\sum_{a \geq b} |\langle m_\nu \rangle_{ab}|^2 + 4c^2 v_\Delta^4}. \quad (2.9)$$

Here we have neglected $\Delta^{--} \rightarrow W^- \Delta^-$, $\Delta^{--} \rightarrow \Delta^- \Delta^-$ since we assumed $m_{\Delta^{--}} \approx m_{\Delta^-}$. Otherwise the Higgs triplet gives too large loop correction to ρ parameter [10]. The estimate of (2.5) and (2.8) indicates that (2.5) is the dominant process. In order to circumvent the ambiguous factors m_Δ and v_Δ , let us consider the ratios

$$\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{ee}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2, \quad (2.10)$$

$$\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{\mu e}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2. \quad (2.11)$$

Here the averaged masses $\langle m_\nu \rangle_{ab}$ ($a, b = e, \mu, \tau$) are defined by

$$\langle m_\nu \rangle_{ab} = U_{a1} U_{b1} m_1 + U_{a2} U_{b2} m_2 + U_{a3} U_{b3} m_3, \quad (2.12)$$

where U_{ai} ($i = 1, 2, 3$) are the components of the MNS lepton mixing matrix and m_i ($i = 1, 2, 3$) are the neutrino masses. We have defined the averaged mass without an absolute symbol unlike the conventional one since h_M is symmetric and complex matrix in general.

3 Lepton Mixing matrix and neutrino mass hierarchy

We know that the MNS lepton mixing matrix U is well approximated by the tribimaximal matrix [11],

$$U = \begin{pmatrix} \sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} e^{i\beta} & 0 \\ -\sqrt{\frac{1}{6}} e^{-i\beta} & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{2}} e^{i(\rho-\beta)} \\ -\sqrt{\frac{1}{6}} e^{-i\rho} & \sqrt{\frac{1}{3}} e^{-i(\rho-\beta)} & \sqrt{\frac{1}{2}} \end{pmatrix}, \quad (3.1)$$

which is supplemented with the Majorana phases, β and ρ . If we neglect the Majorana phases, it is a special case of the $\mu - \tau$ symmetric model [12],

$$U = \begin{pmatrix} c_1 & s_1 & 0 \\ -\frac{1}{\sqrt{2}}s_1 & \frac{1}{\sqrt{2}}c_1 & -\frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}}s_1 & \frac{1}{\sqrt{2}}c_1 & \frac{1}{\sqrt{2}} \end{pmatrix}, \quad (3.2)$$

with $\sin\theta_{12} \equiv s_1 = \sqrt{\frac{1}{3}}$ and $\cos\theta_{12} \equiv c_1 = \sqrt{\frac{2}{3}}$. Equation (3.2) satisfies the $\mu - \tau$ symmetry in more general form than (3.1).

We have assumed so far the tribimaximal approximation (3.1) with a vanishing (1,3) element, that is $\theta_{13} = 0$. In this case we have

$$\text{Br}_{e\mu} = \text{Br}_{e\tau}, \quad \text{Br}_{\mu\mu} = \text{Br}_{\tau\tau}, \quad (3.3)$$

irrespective of θ_{12} . The Majorana phases with $\beta \neq \rho$ break the $\mu - \tau$ symmetry, but the above relations still hold since the corresponding averaged masses are equal up to the overall phase. It should be noticed that we have no approximation for the Majorana phases but have the small effects of θ_{13} and, therefore, of the Dirac phase. Also we may have some small deviation from $\sin\theta_{12} = \sqrt{\frac{1}{3}}$.

In this paper, we first approximate the MNS lepton matrix as (3.1), and proceed to extend it to the $\theta_{13} \neq 0$ case. We obtain a generalized lepton mixing matrix which tends to the tribimaximal one in the limit of $\theta_{13} = 0$,

$$U = \begin{pmatrix} c\sqrt{\frac{2}{3}} & c\sqrt{\frac{1}{3}}e^{i\beta} & se^{i(\rho-\delta)} \\ \left(-\sqrt{\frac{1}{6}} + s\sqrt{\frac{1}{3}}e^{i\delta}\right)e^{-i\beta} & \left(\sqrt{\frac{1}{3}} + s\sqrt{\frac{1}{6}}e^{i\delta}\right) & -c\sqrt{\frac{1}{2}}e^{i(\rho-\beta)} \\ \left(-\sqrt{\frac{1}{6}} - s\sqrt{\frac{1}{3}}e^{i\delta}\right)e^{-i\rho} & \left(\sqrt{\frac{1}{3}} - s\sqrt{\frac{1}{6}}e^{i\delta}\right)e^{-i(\rho-\beta)} & c\sqrt{\frac{1}{2}} \end{pmatrix}, \quad (3.4)$$

where $s \equiv \sin\theta_{13}$, $c \equiv \cos\theta_{13}$, and the δ is the CP violating Dirac Phase.

In numerical analysis, we use experimental values of neutrino mass squared differences [13], Δm_{sol}^2 and Δm_{atm}^2 with assuming the normal and the inverse hierarchy for neutrino masses:

For the normal hierarchy (NH) case, the neutrino masses are given by

$$m_1 = m_0, \quad m_2 = \sqrt{m_0^2 + \Delta m_{sol}^2}, \quad m_3 = \sqrt{m_0^2 + \Delta m_{sol}^2 + \Delta m_{atm}^2}, \quad (3.5)$$

where the smallest neutrino mass is denoted as m_0 .

For the inverse hierarchy (IH) case, the neutrino masses are given by

$$m_3 = m_0, \quad m_2 = \sqrt{m_0^2 + \Delta m_{atm}^2}, \quad m_1 = \sqrt{m_0^2 + \Delta m_{atm}^2 - \Delta m_{sol}^2}, \quad (3.6)$$

where the smallest neutrino mass is denoted as m_0 , as before.

We adopt the center values of the neutrino mass squared differences [13] as

$$\Delta m_{sol}^2 = (8.0 \pm 0.3) \times 10^{-5} \text{ eV}^2, \quad \Delta m_{atm}^2 = (1.9 - 3.0) \times 10^{-3} \text{ eV}^2 \quad (3.7)$$

4 Numerical Calculations

Let us consider the following ratios for the decay widths of the doubly charged Higgs boson to leptonic channels including e and μ flavors

$$\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{ee}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2, \quad (4.1)$$

$$\frac{\Gamma(\Delta^{--} \rightarrow e\mu)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{e\mu}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2. \quad (4.2)$$

The ratios defined by Eqs.(4.1) and (4.2) are functions of three parameters, namely, the smallest neutrino mass m_0 , and the CP violating Majorana phases β and ρ if the mixing angles and the Dirac phase δ are fixed. Therefore, a measurement of the ratio at the LHC will lead us to a constraint among these three parameters. That is, given the ratio of (4.1), and so on, the lower bound of m_0 is obtained as the minimum value of m_0 when we make β and ρ run over all possible values both in the NH and the IH cases for the neutrino mass hierarchy. Note that for the tribimaximal mixing case with $\theta_{13} = 0$ the Dirac phase δ does not appear.

In our previous paper [7], we focused only on the ratio of (4.1) in the tribimaximal mixing case with $\theta_{13} = 0$. This behavior is presented in Fig. 1(a) and Fig. 1(b) for the NH and the IH cases, respectively. The nonshaded area in Fig. 1 is allowed, and is obtained by running over all possible values of β and ρ . Namely, it is shown [7] that the measurement of the ratio at the LHC will fix the lower bound of the smallest neutrino mass m_0 . This is an interesting feature of the HTM.

In the present paper, we consider effects due to $\theta_{13} \neq 0$ and other aspects of the model. In Fig. 2 and Fig. 3, we present allowed regions in the plane of the ratio $\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)}$ and m_0 by taking $\sin^2\theta_{13} = 0.05$ and $\delta = 0$ for the NH and IH cases for the neutrino masses. The nonshaded area is allowed, and is obtained by running over all possible values of β and ρ , as before. We find that effects due to $\theta_{13} \neq 0$ make the lower bound of the neutrino mass m_0 smaller for NH and larger for IH as shown in Fig. 2.

In Fig. 3, we show an enlarged version of Fig. 2. It should be noted that the ratio can be either larger or smaller than one. It is interesting enough that for $\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} < 0.1$ it appears not only the lower bound but also the upper limit of the smallest neutrino mass m_0 for the NH case (Fig. 3(a)). For the IH case (Fig. 3(b)), the range over which the lower bound disappears is enlarged relatively to the case of $\sin\theta_{13} = 0$ of Fig. 2(b).

Considering the other channel $\Delta \rightarrow \mu e$, we also show the results of (4.2) in Fig. 4 and Fig. 5.

So far we have considered the constraint on the smallest neutrino mass m_0 . The decay ratios of the doubly charged Higgs are also served to determine the other MNS parameters. For instance, if we fix m_0 with zero θ_{13} and measure the ratios, we obtain constraints on the Majorana phases of β and ρ , some examples of which are shown in Fig. 6.

One ratio of the decay widths, for instance (4.1), gives one constraint among m_0 , β , and ρ for the $\theta_{13} = 0$ case. Another different ratio, (4.2) also gives an independent another constraint. Therefore if we fix m_0 [14], we can determine the values of β and ρ from the intersections of the contour curves of two independent ratios, some examples of which are shown in Fig. 7.

5 Discussions

We have obtained the lower bound on the smallest neutrino mass m_0 by considering the decay processes of the doubly charged particle to leptonic channels at the LHC. In these calculations, we have approximated the MNS matrix by the tribimaximal one supplemented with the Majorana phases. This approximation has been relaxed to accept nonzero θ_{13} , and we considered its effect on the estimation of m_0 .

However these considerations are not only restricted on the bound of m_0 but also on the constraint on the Majorana phases as shown in Fig. 6 and Fig. 7. Also we may be able to prove the $\mu - \tau$ symmetry by examining (3.3).

The full MNS parameters are widely analyzed by [15] from the various experiments such as single beta decay [14], neutrinoless double beta decay [16] and so on. Now the LHC and long baseline experiments [17] enter into this survey. The constraints from these independently different experiments are crucial to the final determination of the MNS parameters.

The nonshaded area is allowed, and is obtained by running over all possible values of β and ρ . (a) Normal hierarchy case for the neutrino mass with $\sin^2 \theta_{13} = 0$ case. (b) Inverse hierarchy case for the neutrino mass with $\sin^2 \theta_{13} = 0$ case.

Fig. 2 Behavior of $\frac{\Gamma(\Delta^{--} \rightarrow ee)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{ee}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2$ versus m_0 in the case of $\sin^2 \theta_{13} = 0.05$ and $\delta = 0$. The nonshaded area is allowed, and is obtained by running over all possible values of β and ρ . (a) and (b) are for the normal and the inverse hierarchy cases, respectively. The result of Fig. 1 is overwritten to show the effect of θ_{13} .

Fig. 3 The same figure as Fig. 2 but with enlarged scales for the case of $\sin^2\theta_{13} = 0.05$ and $\delta = 0$. (a) and (b) are for the normal and the inverse hierarchy cases, respectively.

Fig. 4 Behavior of $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)} = \left| \frac{\langle m_\nu \rangle_{\mu e}}{\langle m_\nu \rangle_{\mu \mu}} \right|^2$ versus m_0 in the case of $\sin^2\theta_{13} = 0$. The nonshaded area is allowed, and is obtained by running over all possible values of β and ρ . (a) and (b) are for the normal and the inverse hierarchy cases, respectively.

Fig. 5 Behavior of $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu\mu)} = \left| \frac{\langle m_\nu \rangle_{\mu e}}{\langle m_\nu \rangle_{\mu\mu}} \right|^2$ versus m_0 in the case of $\sin^2\theta_{13} = 0.05$ and $\delta = 0$. The nonshaded area is allowed, and is obtained by running over all possible values of β and ρ . (a) and (b) are for the normal and the inverse hierarchy cases, respectively. The result of Fig. 4 is overwritten to show the effect of θ_{13} .

Fig. 6 Contour curves of $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)}$ in the β - ρ plane for the case of $m_0 = 0.1$ eV (panel 1) and $m_0 = 0.01$ eV (panel 2) with $\sin^2 \theta_{13} = 0$. Indices a and b indicate the normal and the inverse hierarchy cases, respectively. For the normal hierarchy cases (a1) and (a2), curves with $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)} < 7.1$ and $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)} < 0.1128$ are allowed for $m_0 = 0.1$ eV and $m_0 = 0.01$ eV, respectively. For the inverse hierarchy cases (b1) and (b2), curves with $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)} < 79.3$ and $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)} < 88$ are allowed for $m_0 = 0.1$ eV and $m_0 = 0.01$ eV, respectively.

Fig. 7 Contour curves of $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)}$ (panel 1) and $\frac{\Gamma(\Delta^{--} \rightarrow e e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)}$ (panel 2) in the β - ρ plane for the case of $m_0 = 0.01$ eV with $\sin^2 \theta_{13} = 0$. Indices a and b indicate the normal and the inverse hierarchy cases, respectively. On condition that we measure both $\frac{\Gamma(\Delta^{--} \rightarrow \mu e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)}$ and $\frac{\Gamma(\Delta^{--} \rightarrow e e)}{\Gamma(\Delta^{--} \rightarrow \mu \mu)}$, we can determine values of the Majorana phase β and ρ from the intersections of the contour curves of (a1) and (a2) for the normal hierarchy case, and of (b1) and (b2) for the inverse hierarchy case, respectively.
